Lab 2

Recursion

In this lab session, we will explore recursion technique.

Instructions

Recursion is a common technique where a difficult problem is broken down into smaller instances of the same problem. By applying the same procedure repeatedly, the problem becomes simpler until reaching a base case that can be solved directly.

1. Basic Concepts

Definition: A function that is defined in terms of itself is called a **recursive function**. A recursive function always has:

- v
 - Recursive Case: The function is redefined in a smaller scope.

For example, the Fibonacci sequence is defined as:

• Base Case: Defines the termination condition.

$$f(n) = \begin{cases} 0, & \text{if } n = 0\\ 1, & \text{if } n = 1\\ f(n-1) + f(n-2), & \text{if } n \ge 2 \end{cases}$$
 (1)

Therefore, the Fibonacci sequence is as follows: 0, 1, 1, 2, 3, 5, 8, etc.

The following C/C++ implementation demonstrates how recursion can be used to compute the Fibonacci sequence follows the mathematical definition above:

```
int fibo(int n)

{
    if (n == 0)
        return 0;

    if (n == 1)
        return 1;

    return fibo(n-1) + fibo(n-2); // Recursive call
}
```

2. Types of Recursion

A recursive function can be classified in many different ways based on the criteria of classification. Below are common types of recursion:

Recursion Call Type

• Direct Recursion: A function calls itself within its body.

```
void func() {
func(); // Calls itself
}
```

• Indirect Recursion: A function calls another function, and that one calls back the original one.

```
void A() {
    B();
    B();
    Void B() {
    A();
    A();
```

Tail and Non-Tail Recursion

• Tail Recursion: The recursive call is the last operation in the function.

```
void tailRecursion(int n) {
    if (n == 0) return;
    cout << n << " ";
    tailRecursion(n - 1);
}</pre>
```

• Non-Tail Recursion: There are computations or calls after the recursive call.

```
void nonTailRecursion(int n) {
   if (n == 0) return;
   nonTailRecursion(n - 1);
   cout << n << " ";
}</pre>
```

Additionally, there are other classification methods, such as classification based on the way the problem size is reduced (linear recursion, binary recursion, multiple recursion), or based on the data structures used (recursion on linked lists, recursion on trees, recursion on graphs), etc.

3. Removing Recursion (Iteration)

A naive recursive implementation is inefficient due to redundant calculations. The C/C++ code below implements a recursive Fibonacci function with a call counter.

For n = 10, the total recursive calls is 177 with many redundant calculations. Indeed, the number of recursive calls grows exponentially in an exponential time complexity $O(2^n)$.

The following code computes Fibonacci numbers using an iterative approach (removed recursion).

```
int fibo_iterative(int n) {
    if (n == 0) return 0;
    if (n == 1) return 1;
    int calc_count = 0, a = 0, b = 1, c;
    for (int i = 2; i <= n; i++) {
        c = a + b;
        a = b;
        b = c;
        calc_count++;
    }
    cout << "Total fibonacci calculating: " << calc_count << "\n";
    return b;
}</pre>
```

The iterative approach only requires a loop of n-1 iterations, making it significantly more efficient than recursion. The time complexity is O(n) and does not involve redundant calculations.

\overline{n}	Recursive Calls $O(2^n)$	Iterative Loops $O(n)$
5	15	3
10	177	9
20	21,891	19
30	2,692,537	29

Table 1: Comparison of recursive and iterative Fibonacci computations.

4. Memoization

A naive recursive implementation is inefficient due to redundant calculations, each call recomputes the same values multiple times. Memoization is a technique that stores previously computed values to avoid redundant computations.

The following C++ code demonstrates the Fibonacci function using memoization with an array to store intermediate results.

```
#include <iostream>
 using namespace std;
4 const int MAX = 100;
5 int memo[MAX];
7 int fibo(int n)
 {
      if (n == 0) return 0;
      if (n == 1) return 1;
      if (memo[n] != -1) return memo[n]; // Check if already computed
      return memo[n] = fibo(n-1) + fibo(n-2);
12
13 }
14
int main()
      fill_n(memo, MAX, -1); // Initialize memoization array
      cout << "Fibonacci(5): " << fibo(5) << endl;</pre>
      return 0;
19
20 }
```

With memoization technique, each Fibonacci number is computed only once and stored for reuse. The time complexity is reduced to O(n) compared to the exponential complexity of naive recursion.

n	Recursive Calls $O(2^n)$	Memoized Calls $O(n)$
5	15	5
10	177	10
20	21,891	20
30	2,692,537	30

Table 2: Comparison of naive recursion and memoization in Fibonacci computation.

By reducing redundant calls, memoization significantly improves performance while retaining the simplicity of recursion.

Exercises

Exercise 1. Factorial

Write a program to compute the factorial of a given non-negative integer n. The factorial of n is defined as:

$$n! = n \times (n-1) \times \cdots \times 1,$$

where 0! = 1.

Input:

• A non-negative integer $n \ (0 \le n \le 20)$.

Output:

• The factorial of n.

Example:

Input	Output
5	120
0	1

Exercise 2. Sum of Digits

Write a program to compute the sum of the digits of a given positive integer.

Input:

• A positive integer n $(1 \le n \le 10^9)$.

Output:

• The sum of the digits of n.

Input	Output
1234	10
9876	30

Exercise 3. Greatest Common Divisor

Write a program to compute the greatest common divisor (GCD) of two integers a and b.

Input:

• Two positive integers a and b $(1 \le a, b \le 10^6)$.

Output:

• The greatest common divisor of a and b.

Example:

Input	Output
24 18	6
100 75	25

Exercise 4. Check Strictly Increasing Array

Write a program to determine whether a given array of integers is strictly increasing.

Input:

- An integer n ($1 \le n \le 100$), the number of elements in the array.
- A sequence of *n* integers $(-10^6 \le a_i \le 10^6)$.

Output:

- Yes if the array is strictly increasing.
- No otherwise.

Input	Output
5	Yes
1 3 5 7 9	
4	No
2 2 3 4	

Exercise 5. Reverse a String

Write a program to reverse a given string.

Input:

• A string consisting of lowercase or uppercase characters.

Output:

• The reversed string.

Example:

Input	Output
hello	olleh
world	dlrow

Exercise 6. Check Palindrome String

Write a program to check whether a given string is a palindrome. A palindrome is a string that reads the same backward as forward.

Input:

• A string consisting of lowercase characters only.

Output:

- Yes if the string is a palindrome.
- No otherwise.

Input	Output
madam	Yes
hello	No

Exercise 7. Generate Permutations

Write a program to generate all permutations of a given set of distinct integers.

Input:

- An integer $n \ (1 \le n \le 10)$ representing the number of elements in the set.
- A sequence of n distinct integers.

Output:

• A list of all possible permutations of the given set, each on a new line.

Example:

Input	Output
3	1 2 3
1 2 3	1 3 2
	2 1 3
	2 3 1
	3 1 2
	3 2 1

Exercise 8. Generate Subsets

Write a program to generate all subsets of a given set of distinct integers.

Input:

- An integer $n \ (1 \le n \le 10)$ representing the number of elements in the set.
- A sequence of n distinct integers.

Output:

- A list of all possible subsets, each on a new line.
- The subsets should be sorted in lexicographical order.

Example:

Input	Output
3	{}
1 2 3	{1}
	{2}
	{3}
	{1,2}
	{1,3}
	{2,3}
	{1,2,3}

Exercise 9. Generate Binary Strings

Write a program to generate all binary strings of length n.

Input:

• An integer n ($1 \le n \le 10$) representing the length of the binary string.

Output:

• A list of all possible binary strings of length n, each on a new line.

Input	Output
3	000
	001
	010
	011
	100
	101
	110
	111

Exercise 10. N-Queens Problem

Write a program to solve the N-Queens problem, which places n queens on an $n \times n$ chessboard such that no two queens attack each other.

Input:

• An integer n $(1 \le n \le 10)$ representing the size of the chessboard.

Output:

- A list of all possible valid solutions.
- Each solution should be represented as an n-length list, where the i-th number represents the column position of the queen in row i.

Example:

Input	Output
4	[2, 4, 1, 3]
	[3, 1, 4, 2]

Regulations

Please follow these regulations:

- You are allowed to use any IDE.
- After completing assignment, check your submission before and after uploading to Moodle.
- Prohibited libraries: <set>, <unordered_set>, <map>, <unordered_map>, <algorithm>, and <bits/stdc++.h>.
- You can use <vector> or any libraries that are not in the prohibited libraries listed above.

Your source code must be contributed in the form of a compressed file and named your submission according to the format StudentID.zip. Here is a detail of the directory organization:

```
StudentID
__Exercise_1.cpp
__...
```

The end.
